

These helper scripts facilitate running ad-hoc observations locally on a GKE node.

The goal is to support using some general-purpose Linux observability tools in the context of a kubernetes node in the GKE platform, letting those tools operate on the scope of a specific target process, container, pod, or the whole host.

Supporting documentation: Ad hoc observability tools on Kubernetes nodes

The above docs include: * CPU profiling, packet captures, **pidstat** usage, and other general-purpose Linux observability tools/techniques * Tips and demos for using these observability tools in GKE * Special considerations for interpreting results in the context of container isolation and resource usage limits
